What is CRUD?

We use CRUD applications every day, most of the time without noticing. They keep us organised, they help digitise business processes, and they're critical to application development.

CRUD refers to the four basic operations a software application should be able to perform:

- **create**
- **read**
- **update**
- **delete.**

A CRUD application is a specific type of software application that can perform these four basic operations (create, read, update and delete). Not all web applications will perform all four operations. For example, when you use iQualify to read this topic, you can read it (R) but you can't alter it (C UD).

Why is CRUD so important?

CRUD is constantly used for tasks related to databases and database design. Software developers can't perform any tasks on a database without CRUD operations.

First, website development, for example, often uses representational state transfer API (RESTful), which is a superset of CRUD using HTTP methods.

Second, CRUD is important for **end users**. Without it, tasks such as registration on websites, creating new users, creating blogs or viewing records would not be possible. Most applications that we use in our everyday life let us add or create new entries, search for existing ones, make changes to the existing ones and delete them.

Letter	Operation	Function	Database operation
C	Create	Insert	INSERT
R	Read	Select	SELECT
U	Update	Edit	UPDATE
D	Delete	Remove	DELETE

[Skip to main content](#)

D	Delete	Delete	DELETE
---	--------	--------	--------

There are two ways we can code for CRUD operations: procedural programming and OOP. The following section will illustrate CRUD operations using both the procedural and OOP approaches. We will first learn about the procedural approach and then move on to learning about the OOP approach.
