

Connecting database to client side 30m

The following code is used to connect with a MySQL database using PHP, a programming language we will start going into more detail on in the next topic. It uses a server name, username and password to tighten the security of the database. This is one of the methods we discussed earlier to provide security to a database.

If you need a refresher about this, we recommend taking a look at the following pages:

Information security technologies and standards →
Database security best practices →

Before we can access data in the MySQL database, we need to be able to connect to the server. The example below shows the code used to connect a database to the server. The code will create a connection and then check that connection.

If you want to try the following code, make sure your previously installed technology stack is currently running. You can use the WordPress database from your CMS work as the example. You can save the following file as 'test.php' in the 'www' or 'htdocs' folder of your technology stack.

The PHP code will begin to make more sense as you work through the next topic.

Watch *PHP tutorial (& MySQL) #25 – Connecting to a database* (Net Ninja, 2019) (5:53) to learn how to create a user and connect a new database to PHP. This video demonstrates the PHP code used to connect to a database in an easy-to-understand tutorial.
