

Creating MySQL database schemas 90m

In this section, we will learn how to create a database schema using phpMyAdmin.

phpMyAdmin is a popular web-based administration tool used to administrate MySQL servers and databases. phpMyAdmin is a web application that is written entirely in PHP.

This section will illustrate how to create a new database and a table on a MySQL server using phpMyAdmin.

To create a database in phpMyAdmin, first check that you have:

- a root or DBA user login to the MySQL server or a user login with permission to create new databases
- access to an instance of phpMyAdmin appropriately configured to administrate the MySQL server.

Watch *Create a database in MySQL PHP tutorial (Krossing, 2023) (12:54)* for step-by-step instructions on how to create a new database.

SHOW TRANSCRIPT

The following guided tutorial will demonstrate how to create a MySQL database schema using phpMyAdmin. In this tutorial, you will create a database schema for a product database that has two tables: a product table and an order table.

Follow the instructions to learn how to create and manage MySQL schemas; this task will help you to do and understand the following:

1. Create a database named db_Product
2. Create two tables – Product table and Order table
3. Create primary and foreign keys and the relationship between the two tables
4. View schema using Designer in phpMyAdmin
5. Insert data (a row) into both tables
6. Delete data (a row) from a table.

Step 1/9: Access and Log in to phpMyAdmin

- Ensure phpMyAdmin is installed as part of your server package (e.g., WAMP, XAMPP, or LAMP). If not, install a package that includes phpMyAdmin.
- Open a browser and go to <http://localhost/phpmyadmin>. If your setup uses a different port, adjust the URL accordingly (e.g., <http://localhost:8080/phpmyadmin>).

You have now successfully:

1. Created a foreign key to establish a relationship between tables (**tbl_product** and **tbl_order**)
2. Visualised the schema and relationships in the **Designer tab**
3. Learned how to add, delete and modify data in your tables.

By following these steps, you can manage relationships and data effectively within your database.

For the next task, you will create a new table on your own.

☒ tbl_Orderlines

Non-Assessed

[Skip to main content](#)

In this activity, you will create a third table, the **tbl_orderlines** table, for the product database case study you've been following. Refer to steps 4 and 5 for help with creating and defining a table.

For the **tbl_orderlines** table, it should contain the fields: Order_Id, Product_Id and Quantity_ordered. The fields should be defined as shown in below.

Field Name	Type
Order_Id	Integer (primary key)
Product_Id	Integer
Quantity_ordered	Varchar

Specify the search engine as InnoDB, then click the save button at the bottom of the page to create tbl_orderlines .
