

[BIT703 Web Technologies](#) / [Contents](#) / Topic 5: Client-side web application development – HTML / Understanding HTML

HTML head and meta elements 30m

The `<head>` element is used at the top of an HTML document and includes metadata about the document. This element is a container for the other elements that are used to format the header section, and it is always written between the `<HTML>` tag and the `<body>` tag. Elements that are used within the `head` element are shown below.

<code><meta></code>	Used to provide information about the web page (description, keywords, language and viewports)
<code><title></code>	Defines the title of the document
<code><style></code>	Defines the style used in the HTML document
<code><link></code>	Typically used to link to an external style sheet
<code><script></code>	Defines the client-side script

We will only discuss the `<meta>` element in this section. We'll look at the other elements later in this course.

The `<meta>` element provides information about the web page that can be used by search engines to categorise the web page and by browsers to display the content. This element uses the attributes shown below.

name	Defines a name for the metadata (that is, description, keywords, author and viewport)
------	---

[Skip to main content](#)

content	Provides the value of the metadata or the header information (http-equiv)
http-equiv	Provides an HTTP header for the information/value of the content attribute
charset	Defines the character encoding for the document. It establishes how the characters are represented by bytes.

Example 5.27 demonstrates how these elements are used.
