How to create an admin panel for a web application

30m

In this next section, you will learn how to create an admin panel by following a case study about an online retail store that needs one.

[Skip to main content](#)

Kākahu is a retail store that now offers its products online. The products they sell are clothes made in New Zealand.

Kākahu approaches you and asks for your help in developing an admin panel for their new online store. They outline the requirements for the admin panel they require, which are listed below.

- It must have an admin interface.
- The dashboard must show an overview of all products, categories and orders.
- Administrators must be able to add, delete and modify the products and categories.
- Administrators should be able to view orders placed as well as the status of these orders.
- Administrators must be able to modify the order status to indicate whether the order has been paid or is pending.

Basically, the admin panel that Kākahu requires must allow the administrators to have full control of their online store.

When developing the admin panel for a web application using PHP, the following initial steps will be carried out.

- Ensure that a XAMPP, WAMP or LAMP server is installed and running on your machine.
- Make sure MySQL is running on your machine and is accessible by phpMyAdmin so you can create a database.
- Create a database and database table/s with the required datatypes for your admin panel. This will enable the admin panel to store and retrieve data.
- Insert sample or test data into your database to complete the creation of your database table in phpMyAdmin.
- Design the admin interface and the layout of the admin interface.

Skip to main content the PHP code used to:

- configure the database and create a database connection with the admin panel
- create the functionality of the admin panel (for example, performing the functions of adding, deleting and modifying products and categories).

We will now go over each of these steps as we create an admin panel for Kākahu. We will provide an explanation of what we are doing at each step of the way as well as the code.

Follow along with us and have a go at creating an admin panel for Kākahu.

The code presented in this section was adapted from Source code and projects (2024). We have modified the layout and functional code and removed Bootstrap from the original source code. **Note: Code from Source Code and Projects can only be used for educational purposes.**

Watch *Simple admin panel In PHP with source code* (Techno Geek, 2022) (10:07) to see an example of an admin panel that was built using the original source code from Source Code & Projects.

Checks and validation

To keep the core code simple, the implementation we are using here does not contain checks and validation for the PHP superglobals `$_GET` and `$_POST`. Also, the initial code has been based on the above 'Simple admin panel' project. This means it is up to you to include the necessary checks and validation. This note also applies to the SQL and PHP MySQL functions where there are no SQL prepared statements used in the example code. The code covered in this topic provides the foundation for Assessment 3, which means there is an expectation that you use suitable checks and validation as covered in the earlier topics.

Since we have modified the layout and functional code, and removed the original Bootstrap code, the admin panel we create for the Kākahu online store will look slightly different to the example admin panel in the video above. To see a visual of what our admin panel will look like at the end, refer to the images below. Use the <> arrows to navigate through the slideshow.

Dashboard of the admin panel for the Kākahu online store
