Test levels 1m

First, we'll learn about test levels, sometimes known as test phases, which are groups of tests that are organised and managed together and applied at different phases of the development. The four main test levels are presented in the interactive below.

Each test level has different types of tests that can be performed to test objectives. There are over 100 different test types – too many to list in this topic. Test types are groups of activities that are designed to test objectives.

The test types you will use will depend on the nature, scope and test objectives of your project.

Test types can be categorised as **functional** and **nonfunctional** types of testing. We will explore functional and nonfunctional testing in detail next, but for now, select each of the tests below for a summary of the different types of tests.

Note that the term **modules** is used in this graphic to describe code modules, individual applications or client and server applications on a network.

Different types of testing can be performed at different test levels. For example, you may perform a:

- ▶ function test at the component level to test the functionality of the components
- ▶ system integration test at the integration level to test the interactions between the systems

Skip to main content

- security test, performance test or usability test at the systems level to test whether the systems are secure, functional and performing well (that is, response times and the amount of traffic the application can handle are both good)
- user acceptance test to test the usability of the application, where you'd look at the ease of use, number of clicks required and navigation for users.

☒ Testing

Non-Assessed

Testing can be applied to any product, not just a web application. Take, for example, a pair of sneakers.

Sneakers are a form of footwear that are designed for physical exercise such as walking and running. Since sneakers are used for physical exercise, they need to be both comfortable and supportive to prevent injuries. Consider your sneakers as you answer these questions:

1. When buying a pair of sneakers, apart from cost, what factors do you check and test before purchasing the sneakers?
2. Considering the different testing types, categorise the factors you would like to check and test into their relevant testing methodologies.
