The UI is that part of the application visible to the user and UI testing is the process of evaluating the functions and on-screen objects of the app to confirm they meet the client requirements and design specifications. These include, for example, drop-down menus, radio buttons, text fields, widgets, toolbars, menu bars, windows and so on.

UIs are vital to enable people who may have lower level computer skills to use a computer as required.

UI testing is performed from the perspective of the user rather than the developer or tester.

Although there is a shift-left trend to start testing earlier in the software development life cycle (SDLC) with unit, integration and API testing, UI testing is important to confirm the usability and visual acceptability of a product. The sooner UI testing can be conducted, the fewer the risks at the end of the development life cycle.

Below is a brief checklist of the elements that should be covered during UI testing. These elements need to be checked against and consistent with the client requirements:

- size, position, dimensions of UI features
- acceptance of inputs to relevant fields
- appropriate error messages
- readable fonts
- alignment
- aesthetics meet modern design practices
- consistent font type and size is used all over the application
- colours and style guide of the product conform to the client specifications
- all icons are designed in one style
- interface contains no visual dialog box inconsistencies
- navigation is intuitively clear
- input fields are of proper size.

Differences between UI testing and usability testing

On the surface, UI and usability appear very similar; they both involve the frontend, user-facing interface without any requirement for access to internal code. However, there is an important difference.

[Skip to main content](#)

UI testing tests the appearance, quality and look and feel of the frontend against the client requirements and design specifications. It also checks these aspects on different configurations and platforms.

Usability testing tests how useable the frontend application is for a non-technical user. Is it intuitive? Can it be easily understood? Can the user easily perform the tasks they need to? Is usability impacted by different screen sizes?

UI testing can be conducted manually or automated by tools such as Selenium. If using automation, this is done in two steps. In the first stage, the test steps are captured as they are performed. In the second stage, those recorded steps are replayed on the Application Under Test (AUT).

☒ Graphic User Interface (GUI) testing

Non-Assessed

In this activity, you will perform a UI test on the following scenario:

Next week, you will be visiting a friend in Auckland, and you will need to rent a car for four days. You will look at bargainrentalcars.co.nz to book the cheapest car available for the length of your stay in the city.

To complete this activity:

1. Decide what UI elements you would like to test on the Bargain Rental Cars website.
2. Devise four test cases to test these elements and write a test script for each. Include any test techniques you use (such as visual models or diagrams).
3. Execute your UI tests and record your results in your test script.

Here is a [template](#) to get you started.

☐ I have completed this task.
